Abstract—The rate of alkaline hydrolysis of ethyl cinnamate was measured over the temperature range of 20°C to 40°C in water-acetone mixture at different composition 30 to 70% (v/v). The influence of solvent variation on reaction rate was examined in term of changes in the activation parameter. Depletion of ΔH° and ΔS° value with simultaneous increase in ΔG° of the reaction in reaction media, reveals that the reaction is Enthalpy domination and Entropy controlled. The Iso-dielectric activation energy (E_d) of reaction was found to decrease from 52.43 to 47.28 which is calculated by plotting log k values against different D. The Values of Iso-kinetic Temperature which is less than 300, clearly indicates that there is no appreciable interaction between solvent and solute present in the reaction media, i.e. reaction is not ion-dipole but ion-molecule type.

Keywords: Activation Parameter; solvent-solute interaction; Iso-kinetic temperature; specific salvation; Iso Dielectric Activation Energy.

I. INTRODUCTION

Solvent play an important role in determining chemical reactivity. In particular, the rate of an elementary chemical reaction may change by orders of magnitude when solvent is changed. Kinetic solvent effect on chemical reaction in different media is correlated in terms of “solvent polarity” which is sums of all the specific and non-specific interaction of the media with initial and transition state”. A large effort has been directed towards understanding such solvent effect and a great deal of progress has been made recently [1-3] both theoretically and experimentally. However, the interpretation of kinetic result on the solvent polarity on medium some time fails and sometime succeeds.

In this note we have extended our studies on kinetic solvent on well-known base catalyzed hydrolysis of Ethyl cinnamate which is important for use of adding to cigarettes and cut tobacco that are used for flavor agent and fragrance agent.

II. EXPERIMENT

The kinetics of base catalyzed hydrolysis of ethyl cinnamate has been carried out volumetric in water-acetone medium having different concentration of solvent (acetone), varying from 30 to 70% (v/v) at five different temperature ranging from 20°C to 40°C at regular interval of 5°C. The specific rate constant calculated using second order reaction was found decrease with increase of acetone content. The iso dielectric Activation energy (E_d) is also calculated with help of slope of log kD against 10^3/T (Tab-I) at constant D and tabulated in Table-II. The iso kinetic temperature was calculated with help of Barclay and Butler relation which come less than 300.

The evaluated thermodynamic activation parameter has been tabulated in Table-III.

III. RESULT AND DISCUSSION

A. Solvent Effect on Rate of Reaction

In order to discuss the variation of specific rate constant values with gradual addition of dipolar aprotic organic solvent (acetone) in reaction media, the value logk is calculated using second order kinetic. The decrease observed in specific rate constant, with increasing concentration of organic solvent is probably due to depletion of Dielectric constant of medium or decreasing polarity of medium as changing from polar water to less polar water-acetone medium. Singh A K [4].

B. Solvent Effect on the Iso- Dielectric Activation Energy of Activation

From the slope of Arrhenius plot (obtain from interpolation of logkD value against 10^3/T at constant D (Tab-I) of reaction media. The value of Iso dielectric activation energy of reaction have been evaluated and represented in Tab-II. (Fig.1). It is obvious that E_d value goes on decreasing from 52.43 to 47.28 KJ/mole with increasing in D value of water –Acetone media, is similar trend to recent finding of Singh R T et al. [5].
The report of Yagil and Anbar[8] indicate that OH− ion of NaOH is hydrated with three molecules of water. In mixed aquo-organic co-solvent mixture, the organic component molecules are expected to contribute to the process of desolvation as they may be regarded as poor anion solver in comparison to water. A similar variation in \( \Delta G^* \) values with increasing mole % of organic co solvent has been reported by Tommila [9] and Cleave [10] and recently Singh A K[11]

The variation of \( \Delta G^* \) with mole% in the solvent are nonlinear and increase smoothly with gradual addition of the solvent (Fig. 2). This finding is indicative of salvation or desolation of reactant as explained by Absolute Reaction rate theory and supported by Elsemongy [12] and Singh A K. [13] From data mention in the table III, the interesting feature comes in the light is that out of all the value of three thermodynamic parameter \( \Delta H^* \), \( \Delta G^* \), and \( \Delta S^* \), the value of \( \Delta H^* \) and \( \Delta S^* \) goes on decreasing with simultaneous increase in \( \Delta G^* \) values with increasing proportion of acetone at all the temperature of the reaction, i.e. from 20º C to 40º C. From the fundamental thermodynamic equation

\[
\Delta G^* = \Delta H^* - T \Delta S^*
\]

it may be inferred that the enhancement in the value of \( \Delta G^* \) with simultaneous depletion in \( \Delta H^* \) and \( \Delta S^* \) value is only possible when the quantitative depletion in the value of \( \Delta S^* \) is less than that found in the values of \( \Delta H^* \) and from this fact, it is concluded that base catalyzed hydrolysis of Ethyl Cinnamate in water-acetone media is Enthalpy dominating and Entropy controlled. In another word, it may also be inferred that in presence of acetone in the reaction media activate the Enthalpy and control over the Entropy of the reaction.

The change found in the value of three thermodynamic Activation parameter also support the fact that initial state of the reaction is desolvated and the transition state is solvated in the similar ways as recently reported by Singh A K, [14]

To explain the solvent effect on the thermodynamic parameters these three values namely \( \Delta G^* \), \( \Delta H^* \) and \( \Delta S^* \) were plotted against mole% of acetone in reaction shown in Fig. 2 3and 4 respectively. The nonlinear variation in \( \Delta H^* \) and \( \Delta S^* \) give information specific salvation taking place in water-acetone as reported by Saviil et al. [15]

C. Solvent Effect and Thermodynamic activation parameters

The thermodynamics Activation parameter such as Enthalpy of Activation (\( \Delta H^* \)), Entropy of Activation (\( \Delta S^* \)) and free energy of Activation (\( \Delta G^* \)), are better indicator of the solvent effect exerted by the solvent on the solvolysis reaction. These thermodynamics Activation parameter has been calculated with help of Wyne-Jones Eyring[6] equation and absolute rate theory[7] and placed in Tab-III.

On careful observation of the data Tabulated in table III (water-acetone) \( \Delta G^* \) value in case of water-acetone increases from 92.09 to 94.26 KI/mole with change of proportion of solvents from 20% to 70% at 20º C. Though the enhancement is not large, however it is quite considerable.

D. Evaluation of Iso-kinetic Temperature and Solvent-Solute Interaction

In the light of Barclay and Butler [15] relationship between Enthalpy and Entropy of Activation, which is as follows

$$\delta m(\Delta H^*) = \beta \delta m(\Delta S^*)$$

It is straight line equation representing the relationship between Enthalpy and Entropy of Activation. β is the Iso-kinetic temperature.

From the data available in the table IV the plot of ΔH* and ΔS* in the solvent system in Fig. 5 and from the slope of straight line, the value of Iso-kinetic temperature was calculated to be 244 (water-acetone) and which is less than 300.

From the value of Iso-kinetic temperature which is much less than 300, it is concluded that there is slow change in the structure of the reactant or in the solvent or in due to weak interaction between solvent and solute present in the reaction media in similar way as reported by Lefler[16] Our this conclusion has been recently supported by Singh A. K.[18].

IV. CONCLUSION

The result of this work indicate that the rate of hydrolysis of Ethyl cinnamate decreasing trend at all temp witch appear that transition state is more desolvated than initial state. The enhancement in the value of and ΔG* with simultaneous depletion in ΔH* ΔS* for the hydrolysis ethyl inanimate in water-acetone is enthalpy dominating and Enthalpy control. The linear plots obtained by plotting logk as function of D represent the different electrostatic interaction for the ion-dipole as well as dipole - dipole reaction. The much less value (>300) of iso kinetic temps indicate weak interaction between solvent and solute.

ACKNOWLEDGMENT

My special gratitude to my supervisor Prof. R T Singh for his proper guidance and thanks to my friend Dr. Ajit, Dr. Parag and Mr. L K Tiwari for his cooperation during preparation of this content. I am Thankful to Mrs. Rolly Gupta & Mss. Akansha for their assistance.
